

Simulating Treatment for Obesity-Induced Type II Diabetes with GLP-1 Agonist Drugs

By Eli Bullock-Papa

In this presentation:

1. What is diabetes
2. Overview of how it forms
3. A more complete model (we'll breeze through it this time)
4. My Work

What is Diabetes?

Diabetes Overview

Complex condition **diagnosed** by having **too much glucose in your blood**

Major Components Overview

Blood Glucose: sugar your body produces when you eat.

Insulin: a hormone produced to tell cell they should absorb glucose from the bloodstream.

Beta cells: cells in the pancreas that produce insulin.

Type 2 Diabetes

Type 2 diabetes

In type 2 diabetes, the pancreas makes some insulin but it is not working as well as it used to.

How does it
develop?

Diabetes Development and Obesity

Views have **changed over time** but this is the modern overview of **how we think Type 2 Diabetes (T2D) is developed in youth** (people under 40):

1. Due to the combination of diet and lack of exercise, a person starts to **gain excessive weight**, potentially leading to obesity.
2. In response to high blood sugar levels, the **pancreas produces more insulin** than normal to try to lower blood sugar levels.

Diabetes Development and Obesity

3. The body **begins to develop insulin resistance as a protective response**. It's theorized that this resistance helps shield the body's cells from excessive sugar intake and the stress of high insulin levels
4. The insulin resistance means that cells aren't taking up all of the blood glucose, and **blood sugar remains high** even with high insulin levels.
5. High blood sugar levels **keep beta cells producing insulin levels in overdrive**.
6. Over long stretches of time, this overwork causes **beta cells to begin dysfunctioning or even die**.
7. This plus continued insulin resistance means **blood glucose levels continue to spiral upwards**

A more complete
model

Glucose to β -cell Mass: The effect can be positive or negative depending on the circumstances. In this context, an optimal level of glucose is necessary to maintain β -cell mass. However, persistently high glucose levels (hyperglycemia) can lead to β -cell dysfunction and loss of mass.

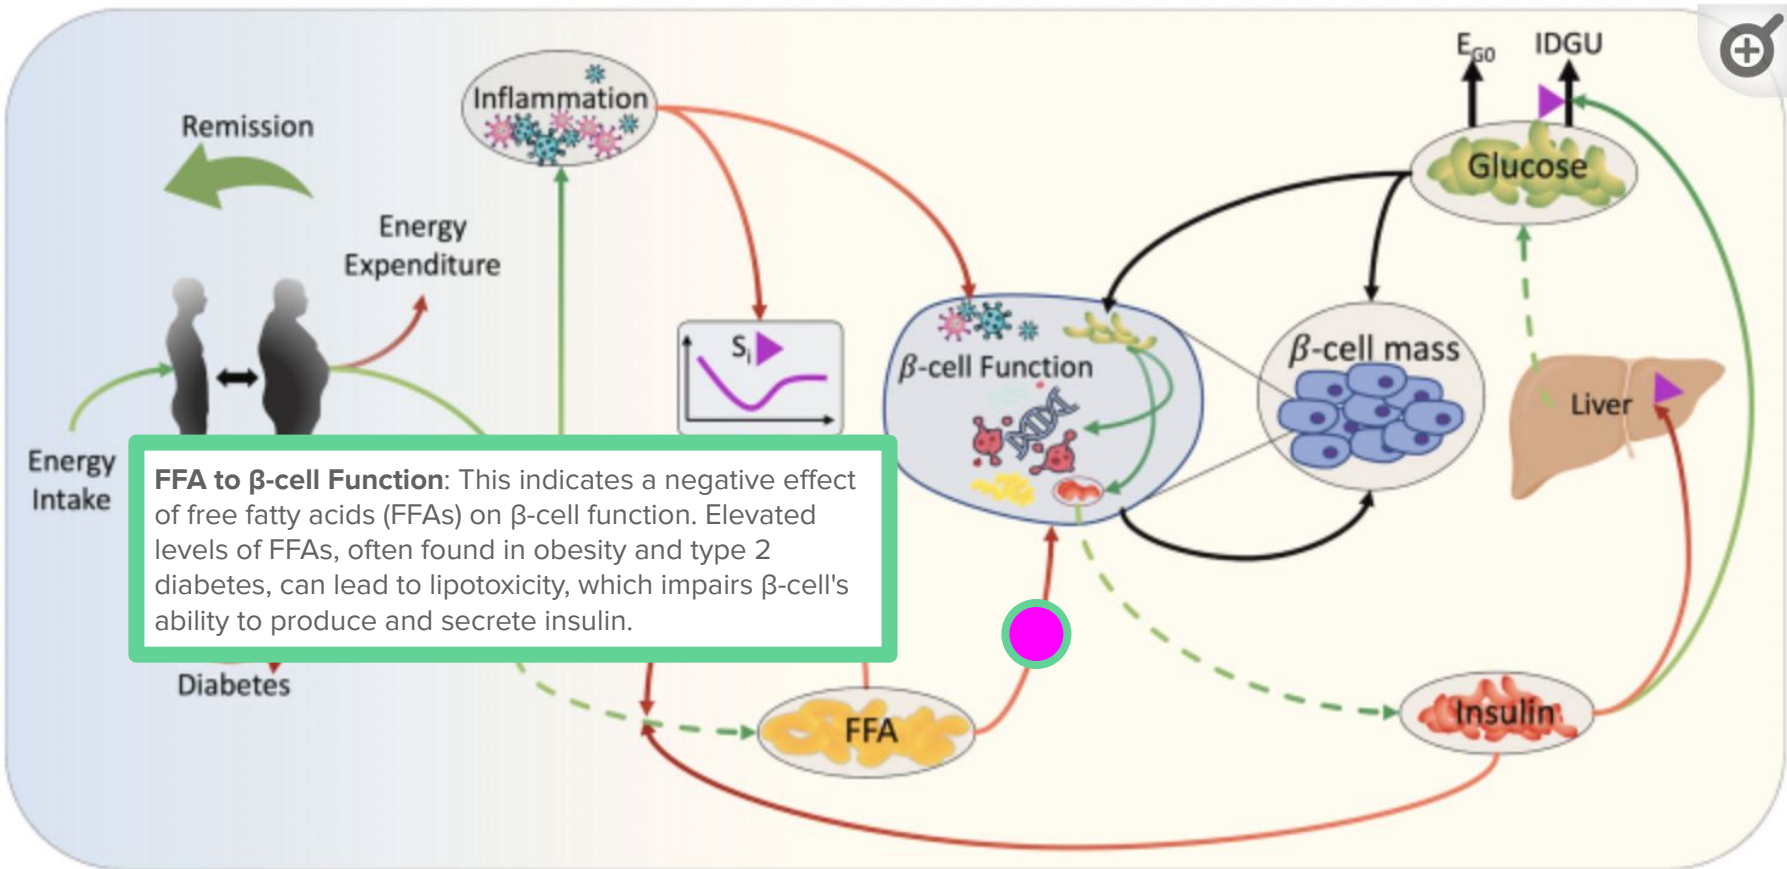

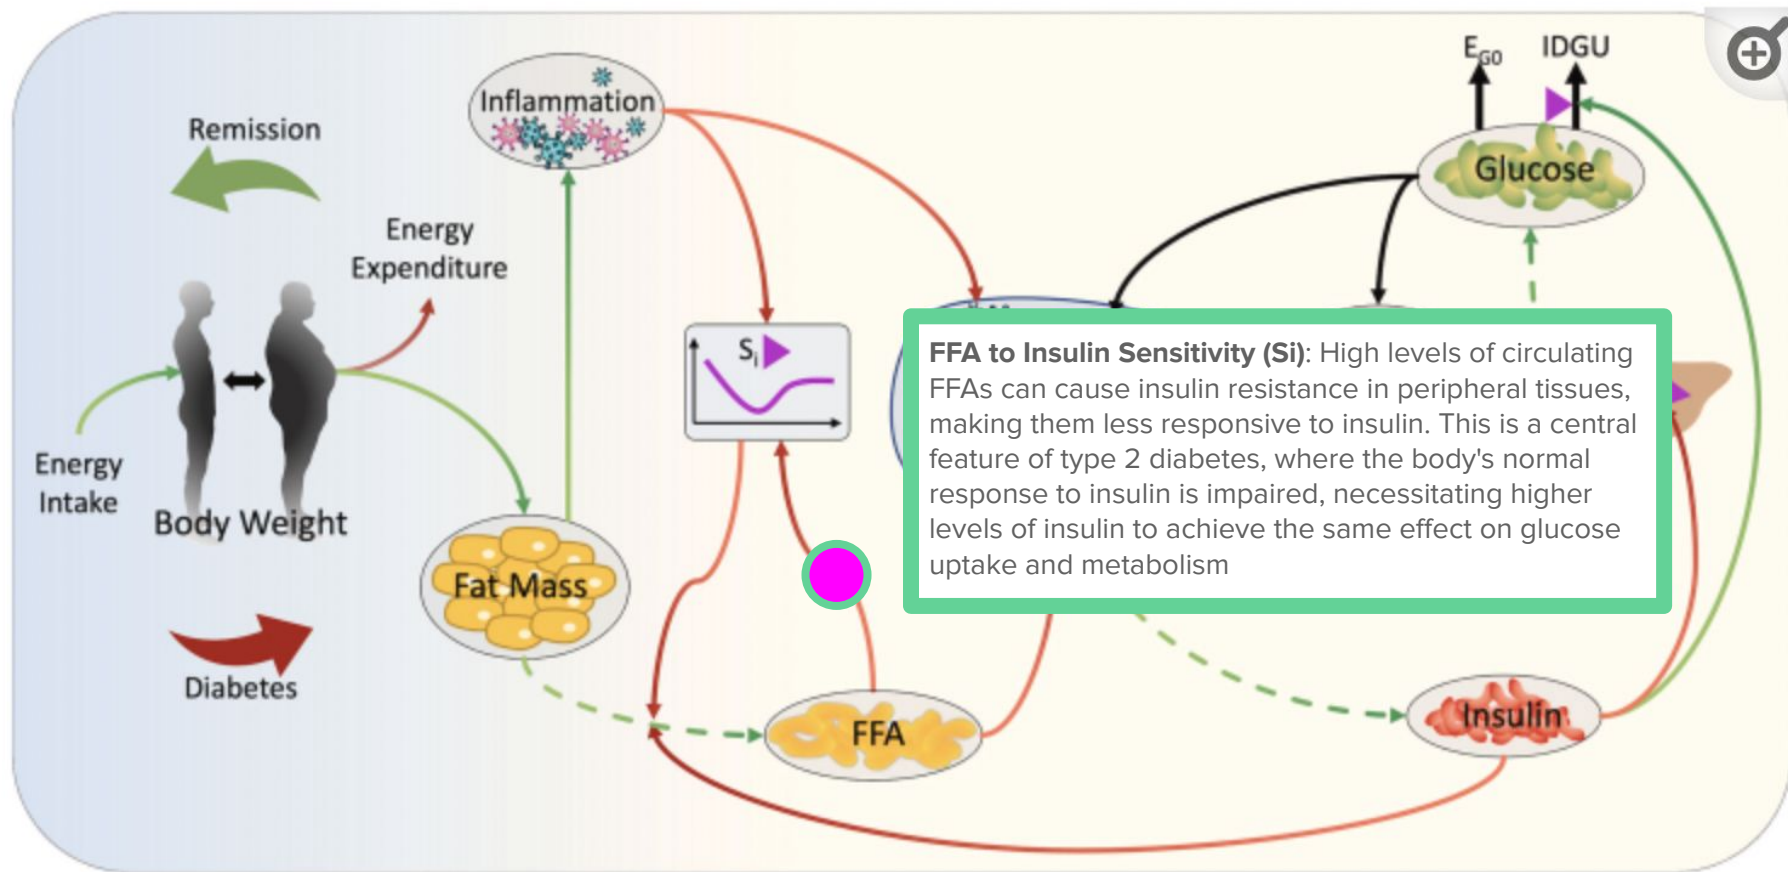

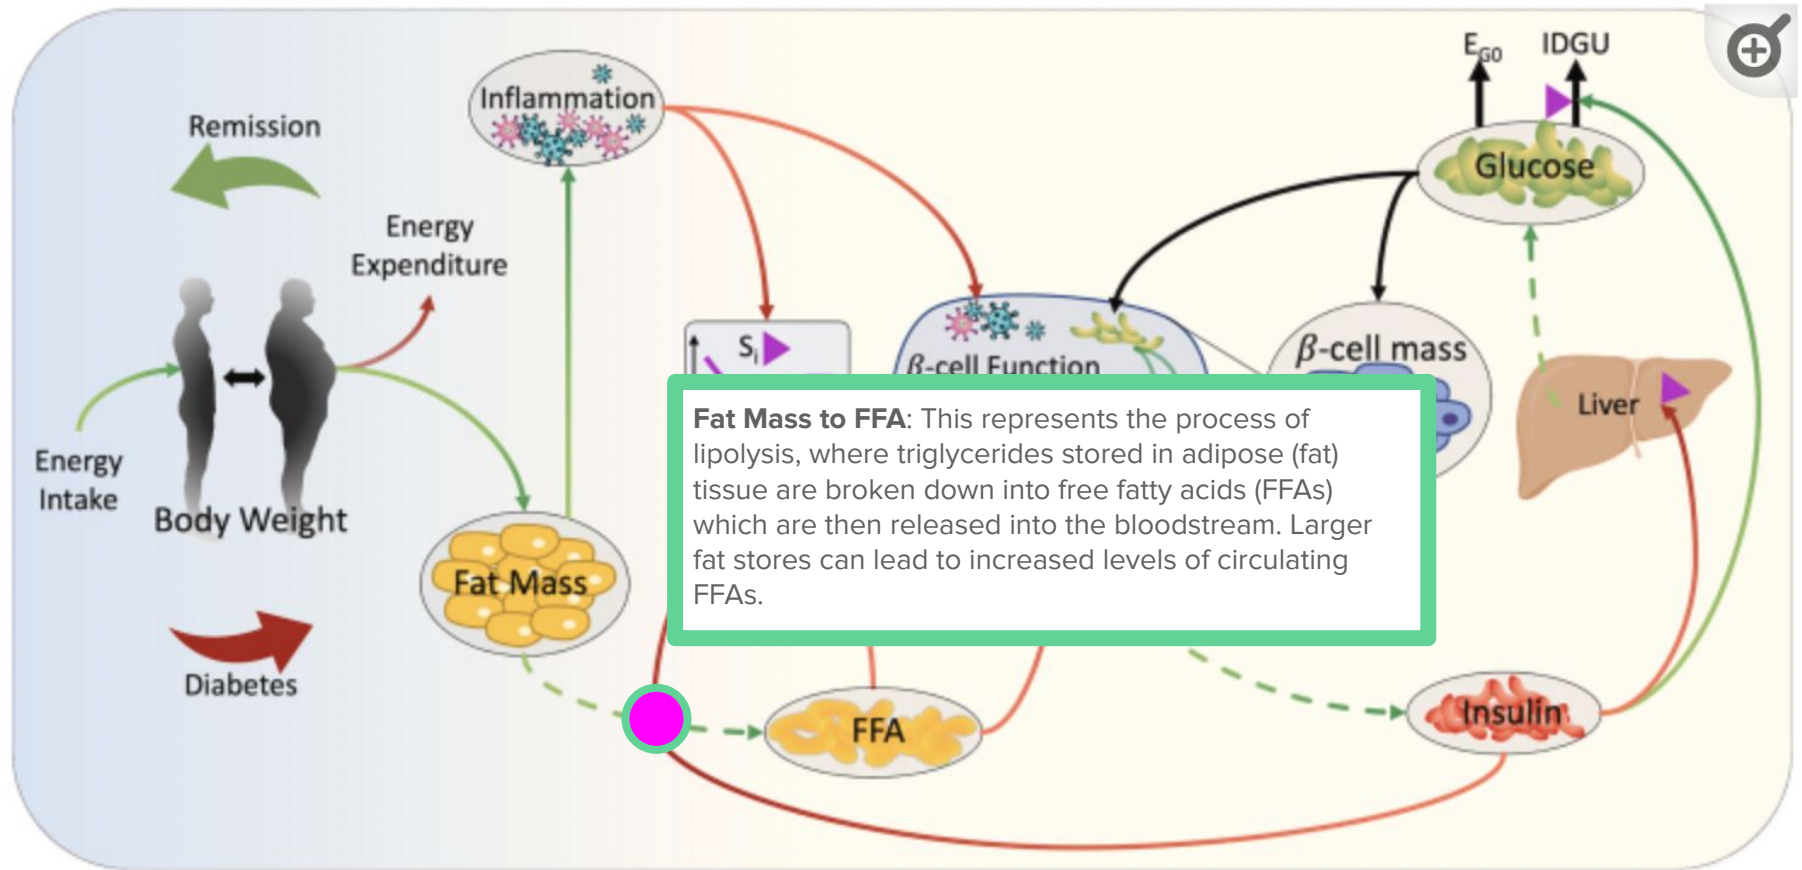

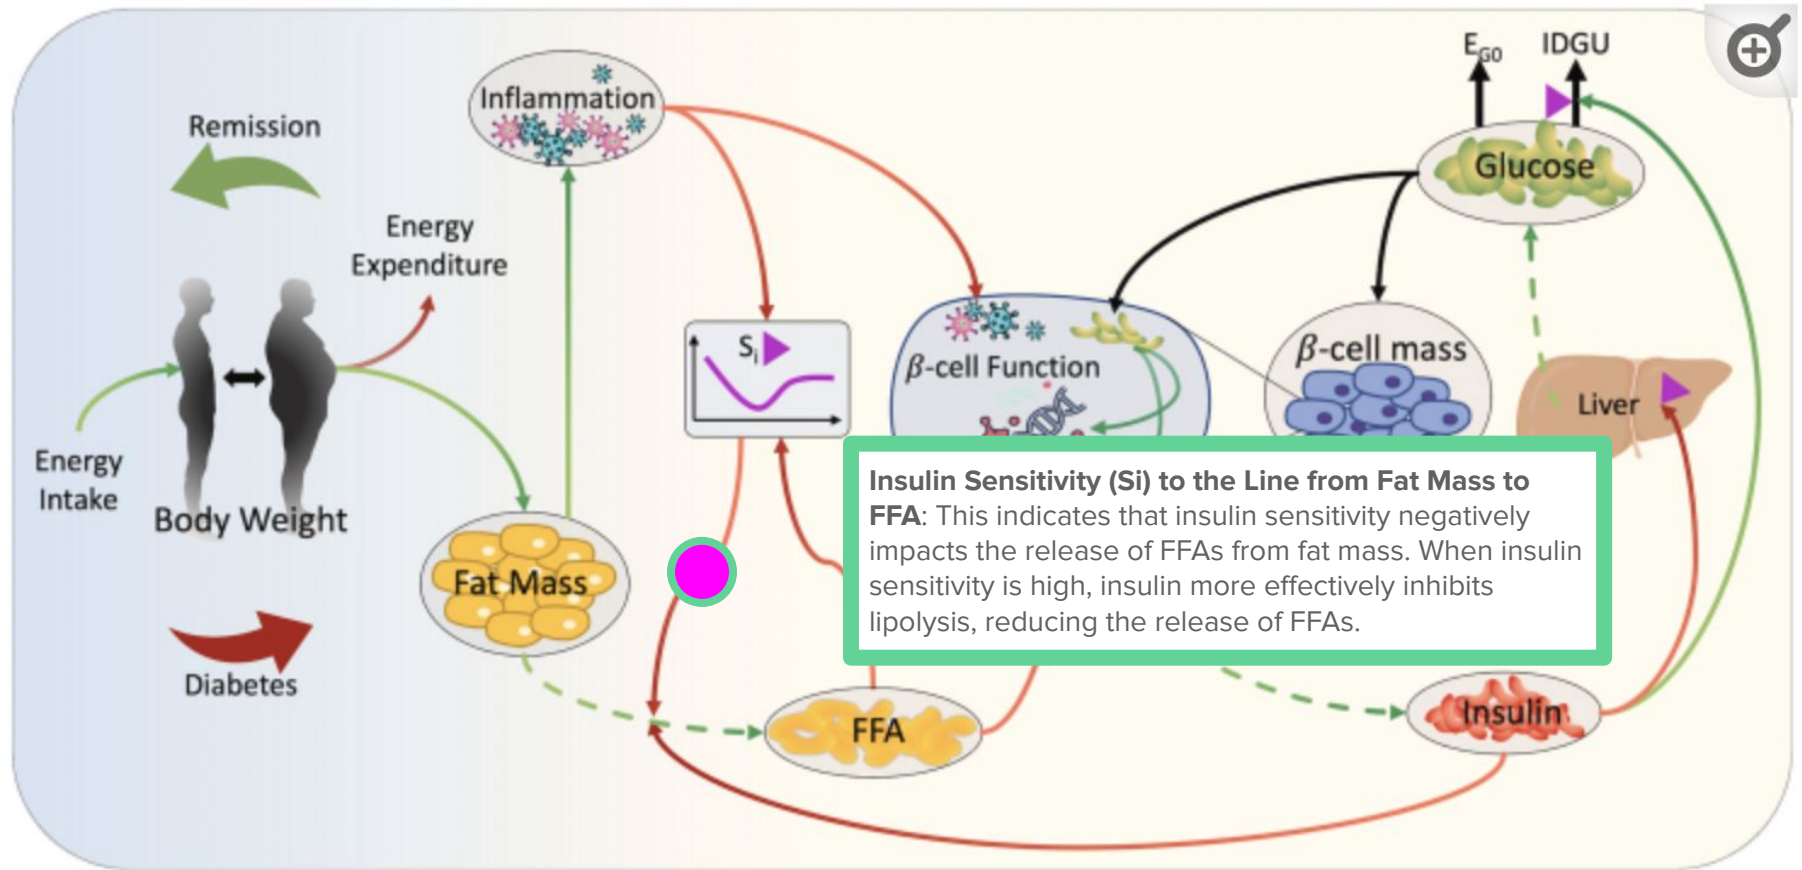

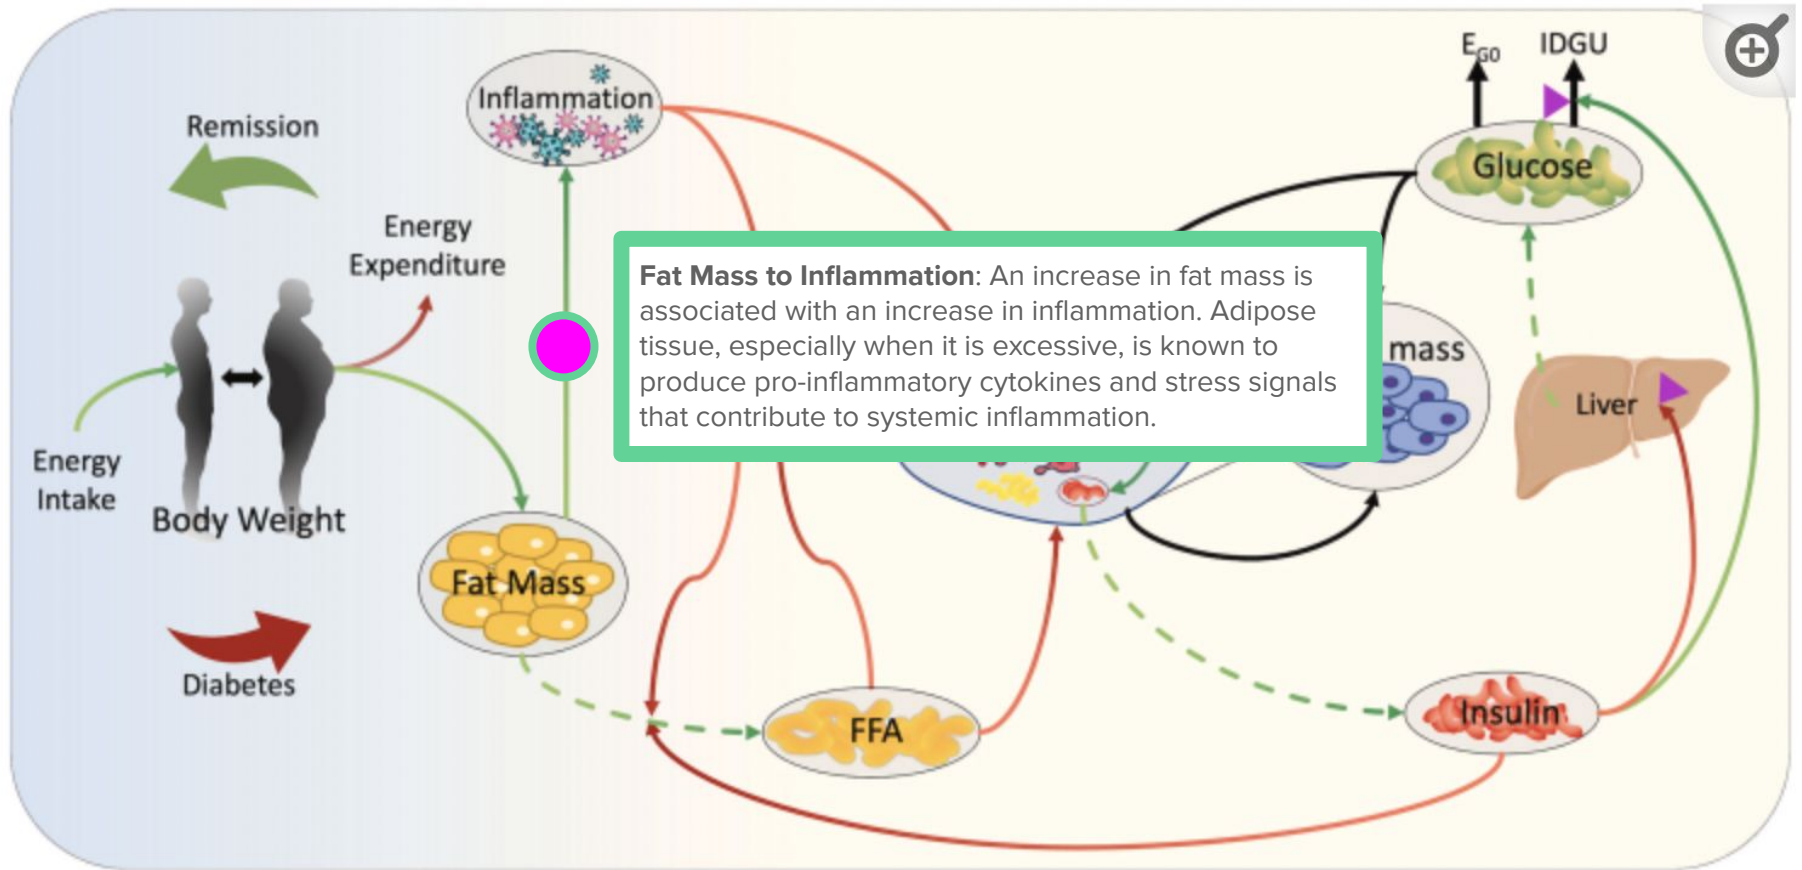

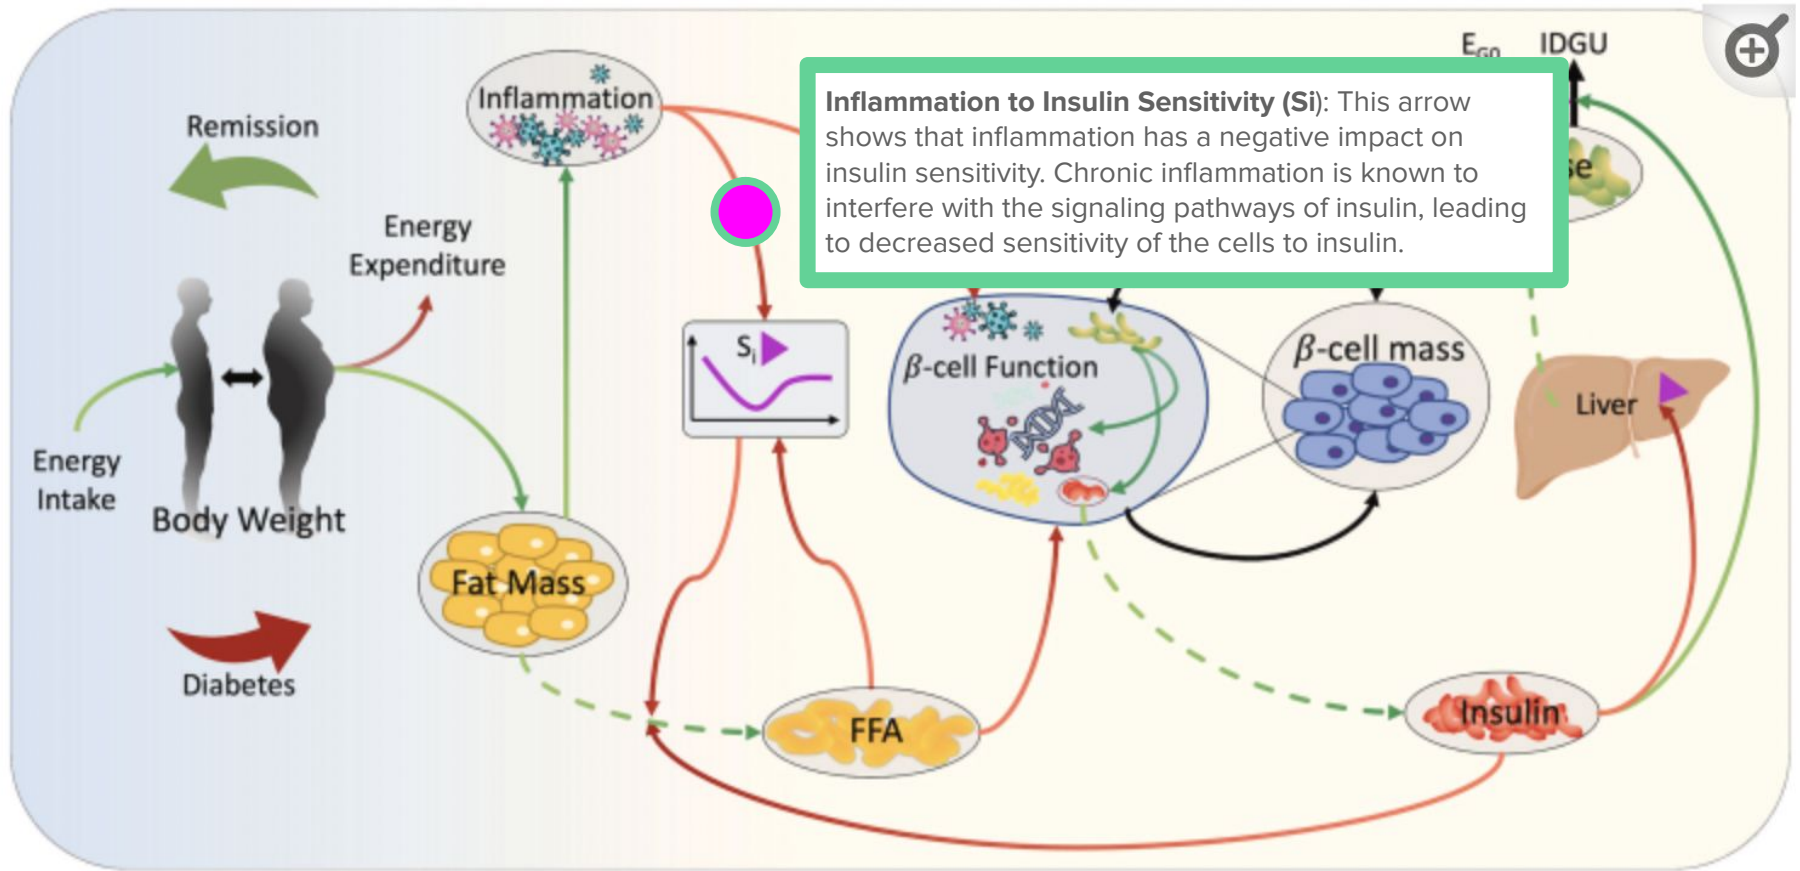

Remission

Diabetes

Inflammation to β -cell function: represents the adverse impact of inflammation on the pancreas's β -cells. Elevated levels of pro-inflammatory cytokines can trigger cellular stress responses, lead to programmed cell death, and interfere with insulin production and secretion processes, collectively contributing to the decline in the cells' ability to produce and regulate insulin effectively.

Experimental data on GLP-1 agonist Wegovy

Patients taking Wegovy® achieved¹

~15% or **~35lb**
Mean Weight Loss Reduction

at 2 years

vs 2.6% (~6 lb) weight loss with placebo

Mean baseline body weight:
Wegovy®=232.8 lb; placebo=234.8 lb.
Mean baseline BMI: 38.5 kg/m².

Data issues

The published drug test results do not show how many calories participants ate, instead they focused on weight as an endpoint. Therefore, I can't get experimental information on calorie reduction (or an accompanying timeline).

Therefore, I had to estimate calorie reductions in order to replicate the weight findings

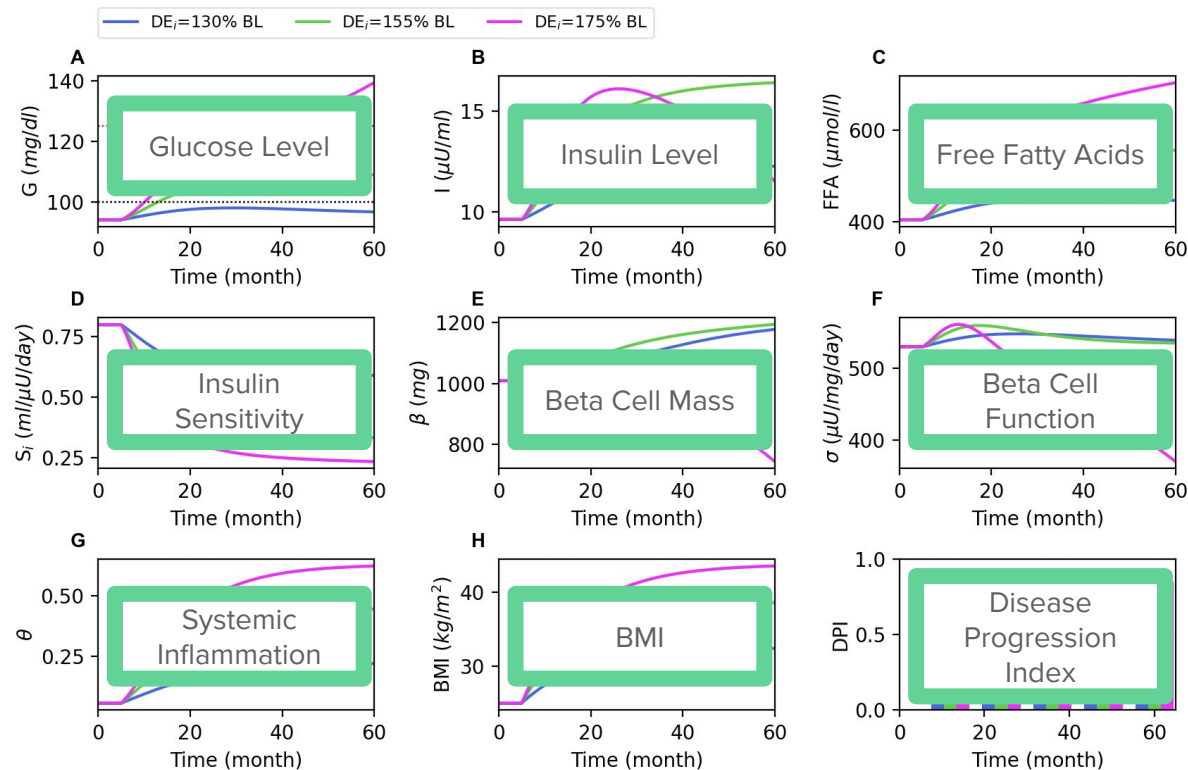

Defining a function to mimic GLP-1 Agonist treatment

```
def adjust_for_wegovy(t, pars):  
    if t > 365: # Assuming drug introduction after one year, expressed in days  
        ramp_duration = 180 # duration over which the drug effect ramps up in days  
        ramp_factor = min((t - 365) / ramp_duration, 1) # caps at 1 when the full effect is reached  
        pars['inc_i1'] = max(pars['inc_i1'] - ramp_factor, pars['inc_i1'] - 0.15) # Gradually apply the reduction in caloric intake
```

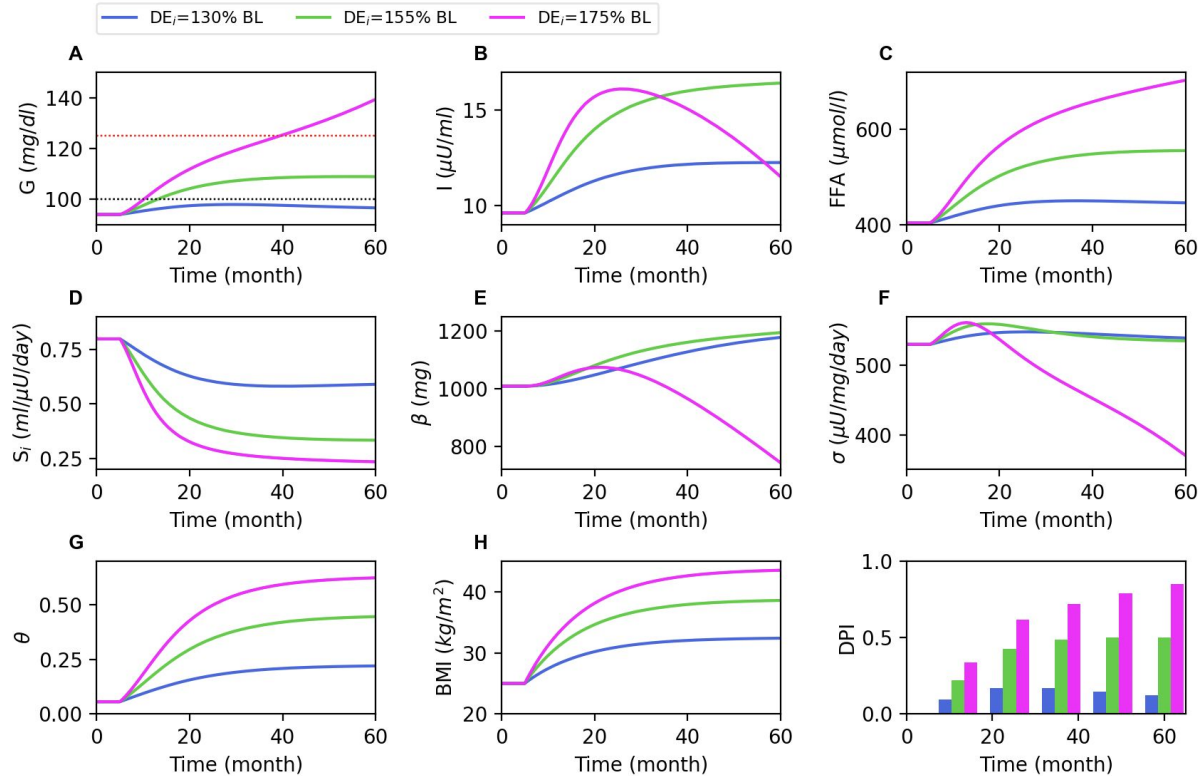

Important parts of this function

- Treatment start time (in this case 365 days)
- Ramp duration to increase to full dose (in this case 180 days)
- Minimum calorie intake (in this case 15% below the original amount)

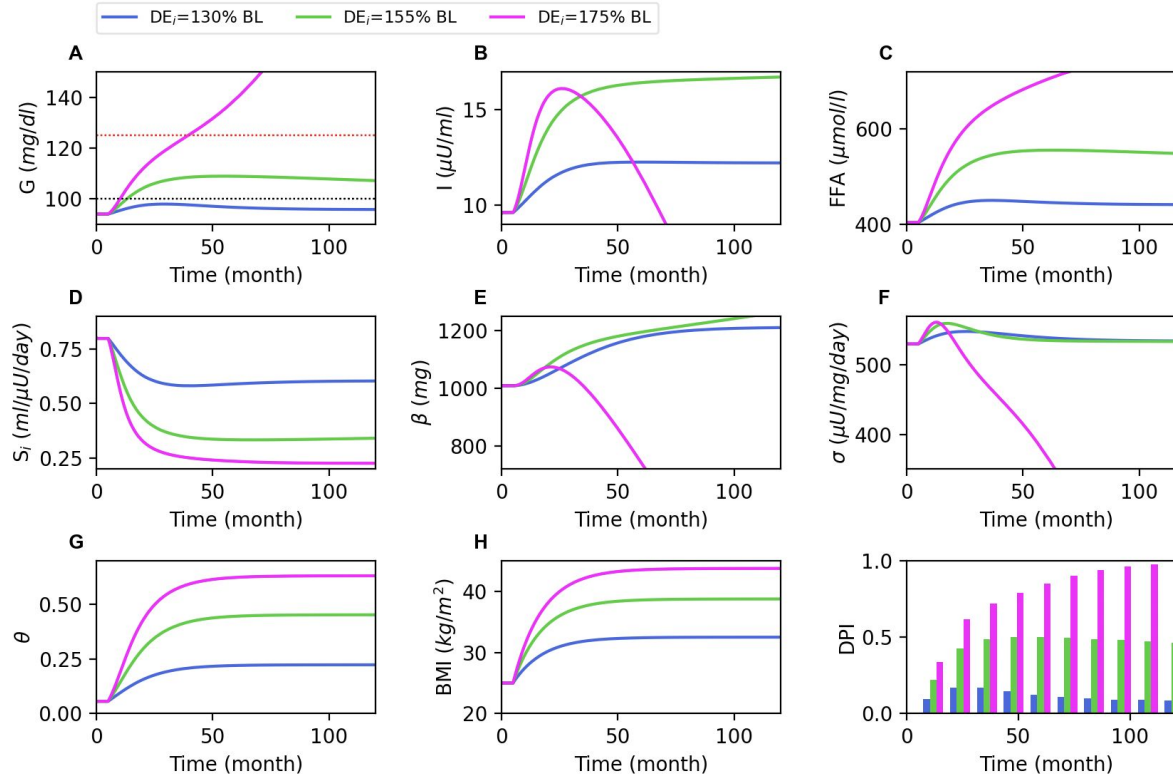

Reproducing the results in the paper

Reproducing the results in the paper

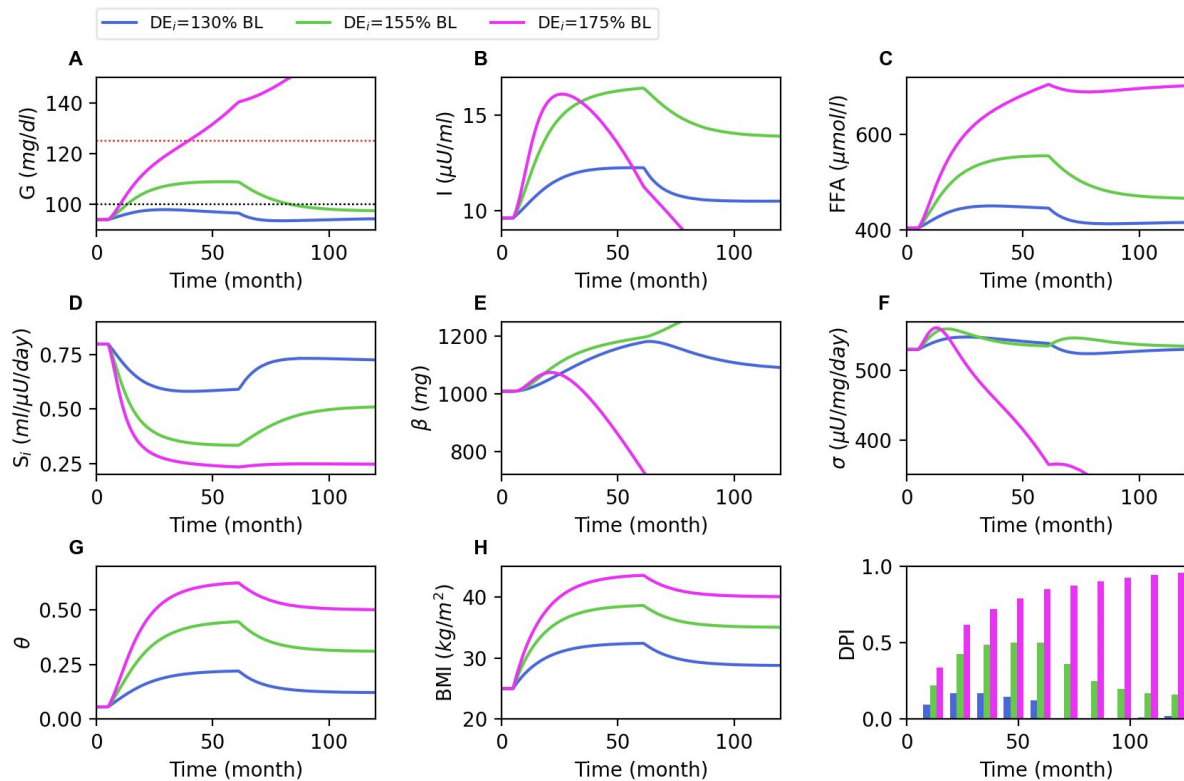

Extending the results in the paper

Doubled length of time to 10 years

Trying to replicate Wegovy medical trials

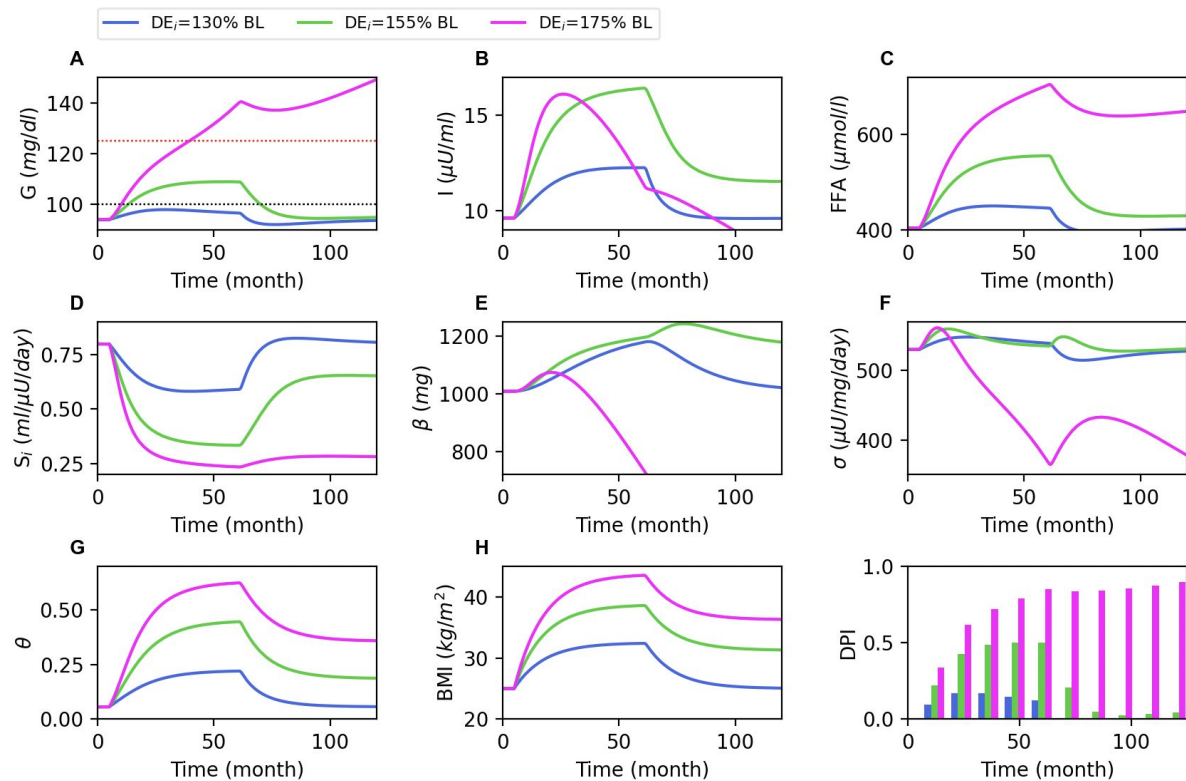

Treatment start time
- Year 5

Ramp duration
- 120 days

Ending calorie intake
- 15% less than
what they've
been eating for
the past 5 years

Trying to replicate Wegovy medical trials

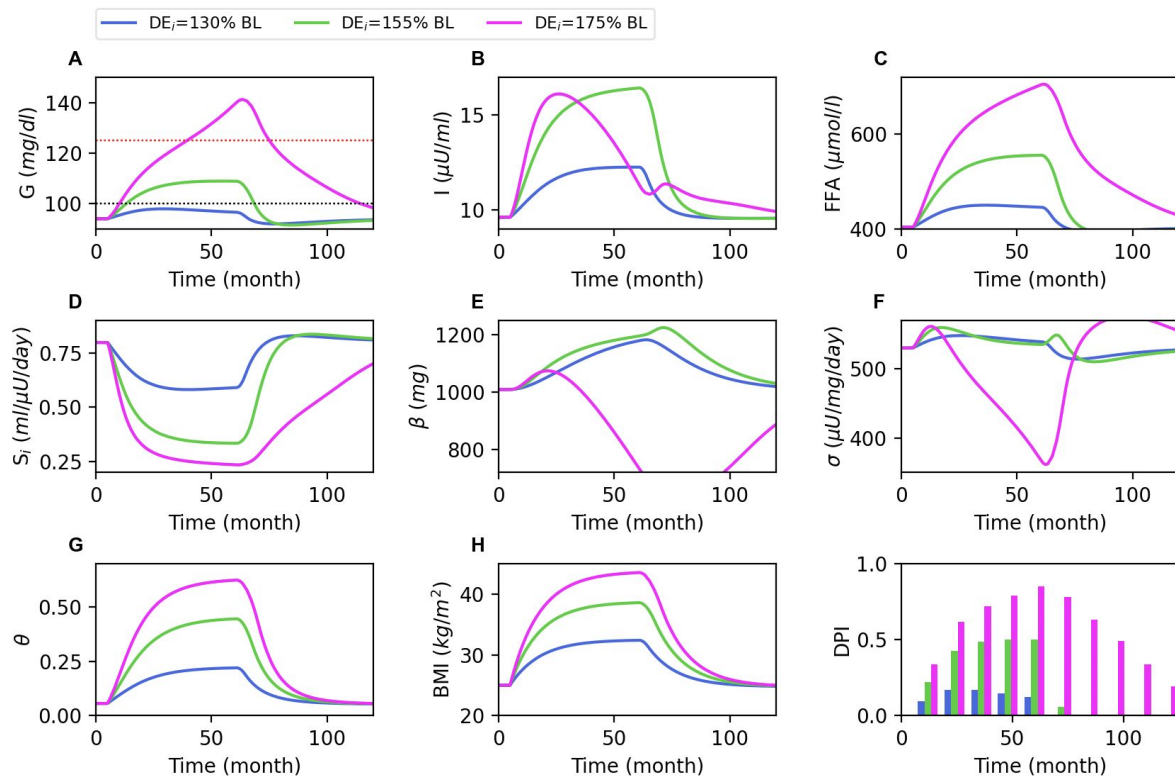

Treatment start time
- Year 5

Ramp duration
- 120 days

Ending calorie intake
- 30% less than
what they've
been eating for
the past 5 years

Trying to replicate Wegovy medical trials

Treatment start time
- Year 5

Ramp duration
- 365 days

Ending calorie intake
- 1% calorie deficit
below baseline
needs based on
height

Important Caveats

- Wegovy and other GLP-1 agonists have additional blood sugar controlling effects **independent** of weight loss effects.
- Anecdotally at least, people with **severe** diabetes (200mg/dl +) have seen their blood sugar lowered to more reasonable levels in less than a year

Any Questions?
